

Thermodynamics

- First and second principles of thermodynamics
- Clausius-Duhem, dissipation
- Thermoelasticity
- Standard models
- Kinematic nonlinear hardening
- Heat dissipation under cyclic loadings

-Track the energy in the plastic process-

First and second principle of the thermodynamics

- first principle :

$$\frac{dE}{dt} = \int_D \rho \frac{de}{dt} dV = \dot{W}_e + \dot{Q}$$

(\dot{W}_e = power of the external load, \dot{Q} = heat received, E (e) specific internal energy, kinetic energy neglected).

With \underline{q} the heat flux vector and r the volumic heat :

$$\rho \frac{de}{dt} = \sigma_{ij} \dot{\varepsilon}_{ij} + (r - \operatorname{div}(\underline{q}))$$

- second principle :

$$\frac{dS}{dt} \geq \int_D \frac{r}{T} dV - \int_{\partial D} \frac{q_i n_i}{T} dS$$

then :
$$\int_D \left(\rho \frac{ds}{dt} - \frac{r}{T} + \operatorname{div} \left(\frac{\underline{q}}{T} \right) \right) dV \geq 0$$

(entropy (specific) S (s), \underline{n} outward normal to the surface ∂D of the domain)

Dissipation

Clausius-Duhem inequality

(the specific free energy is $\psi = e - Ts$)

$$\sigma_{ij}\dot{\varepsilon}_{ij} - \rho\frac{d\psi}{dt} - \rho s\dot{T} - \frac{1}{T}\underline{\mathbf{q}} \cdot \underline{\mathbf{grad}}(T) \geq 0$$

Application of the method of local state:

ψ depend on temperature and *state variables* α_i

$$\frac{d\psi}{dt} = \frac{\partial\psi}{\partial T}\dot{T} + \frac{\partial\psi}{\partial\alpha_i}\dot{\alpha}_i$$

$$s = -\frac{\partial\psi}{\partial T}$$

$$\sigma_{ij}\dot{\varepsilon}_{ij} - \rho\frac{\partial\psi}{\partial\alpha_i}\dot{\alpha}_i - \frac{1}{T}\underline{\mathbf{q}} \cdot \underline{\mathbf{grad}}(T) \geq 0 \quad (4)$$

Intrinsic dissipation Φ_1 , thermal dissipation Φ_2 :

$$\Phi_1 = \sigma_{ij}\dot{\varepsilon}_{ij} - \rho\frac{\partial\psi}{\partial\alpha_i}\dot{\alpha}_i \quad \Phi_2 = -\frac{1}{T}\underline{\mathbf{q}} \cdot \underline{\mathbf{grad}}(T)$$

Heat equation

Decoupling of intrinsic and thermal dissipations, each of them must be positive

- Fourier's law :

$$\underline{\mathbf{q}} = -k(T, \alpha_i) \underline{\mathbf{grad}}(T)$$

- heat equation in presence of mechanical strain:

$$\operatorname{div} \left(k \underline{\mathbf{grad}}(T) \right) = \rho C_\varepsilon \dot{T} - r - \sigma_{ij} \dot{\varepsilon}_{ij} + \rho \left(\frac{\partial \psi}{\partial \alpha_i} - T \frac{\partial^2 \psi}{\partial T \partial \alpha_i} \right) \dot{\alpha}_i \quad (5)$$

(with $C_\varepsilon = T \frac{\partial s}{\partial T}$ specific heat at a constant deformation)

Thermo-elasticity (1)

- Zero elastic strain for $\tilde{\sigma}^I$, zero thermal strain for T^I
- The state variable is elastic strain: $\alpha_I \equiv \tilde{\varepsilon}^e$ in intrinsic dissipation
- No dissipation for an elastic isothermal perturbation around equilibrium, then

$$\Phi_1 = \tilde{\sigma} : \dot{\tilde{\varepsilon}}^e - \rho \frac{\partial \psi}{\partial \tilde{\varepsilon}^e} : \dot{\tilde{\varepsilon}}^e = 0$$

This provides a definition for stress:

- Two state variables, two energetically conjugated variables:

State variable	Conjugated variable
T	entropy $s = -\frac{\partial \psi}{\partial T}$
$\tilde{\varepsilon}^e$	stress $\tilde{\sigma} = \frac{\partial \psi}{\partial \tilde{\varepsilon}^e}$

ψ is a thermodynamic potential which characterizes reversible processes

Thermo-elasticity (2)

Assume the following form for free energy:

$$\begin{aligned}\rho\psi = \tilde{\boldsymbol{\sigma}}^I : \tilde{\boldsymbol{\varepsilon}}^e + \frac{1}{2}\lambda(\text{Tr } \tilde{\boldsymbol{\varepsilon}}^e)^2 + \mu \tilde{\boldsymbol{\varepsilon}}^e : \tilde{\boldsymbol{\varepsilon}}^e - 3K\alpha \text{Tr } \tilde{\boldsymbol{\varepsilon}}^e(T - T^I) \\ - \frac{1}{2} \frac{\rho C_\varepsilon}{T^I} (T - T^I)^2\end{aligned}\tag{1}$$

The stress is then:

$$\begin{aligned}\tilde{\boldsymbol{\sigma}} = \rho \frac{\partial \psi}{\partial \tilde{\boldsymbol{\varepsilon}}^e} = \tilde{\boldsymbol{\sigma}}^I + \lambda \text{Tr } \tilde{\boldsymbol{\varepsilon}}^e \tilde{\boldsymbol{I}} + 2\mu \tilde{\boldsymbol{\varepsilon}}^e - 3K\alpha(T - T^I)\tilde{\boldsymbol{I}} \\ \tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}^I = \lambda (\text{Tr } \tilde{\boldsymbol{\varepsilon}}^e - 3\alpha(T - T^I)) \tilde{\boldsymbol{I}} + 2\mu \tilde{\boldsymbol{\varepsilon}}^e\end{aligned}$$

Variation of specific entropy:

$$\rho s = -\rho \frac{\partial \psi}{\partial T} = 3K\alpha \text{Tr } \tilde{\boldsymbol{\varepsilon}}^e + \frac{\rho C_\varepsilon}{T^I} (T - T^I)$$

Temperature changes for elastic loadings

Temperature variation related to volume change:

$$(T - T^I) = -\frac{3K\alpha T^I}{\rho C_\varepsilon} \varepsilon_{ll}^e$$

Cooling during tension

Loading curves

- isothermal : $\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}^I = \lambda \text{Tr } \tilde{\boldsymbol{\varepsilon}}^e \tilde{\boldsymbol{I}} + 2\mu \tilde{\boldsymbol{\varepsilon}}^e$
- adiabatic : $\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}^I = \left(\lambda + \frac{9K^2\alpha^2 T^I}{\rho C_\varepsilon} \right) \text{Tr } \tilde{\boldsymbol{\varepsilon}}^e \tilde{\boldsymbol{I}} + 2\mu \tilde{\boldsymbol{\varepsilon}}^e$

No change on shear modulus, variation of the axial component

Extension to dissipative processes

- Definition of state variables α_I and of hardening variables Y_I

State variable	Conjugated variable	
T	$s = -\frac{\partial \psi}{\partial T}$	entropy
$\tilde{\varepsilon}^e$	$\sigma = \rho \frac{\partial \psi}{\partial \tilde{\varepsilon}^e}$	stress
α_I	$Y_I = \rho \frac{\partial \psi}{\partial \alpha_I}$	state variables

- The intrinsic dissipation can be rewritten:

$$\Phi_1 = \sigma : \dot{\varepsilon}^p - Y_I \dot{\alpha}_I = Z \dot{z}$$

with : $Z = \{\sigma, Y_I\}$; $z = \{\dot{\varepsilon}^p, -\dot{\alpha}_I\}$

Standard models (1)

- A model is *standard* if one can find a potential $\Omega \equiv \Omega(Z)$ such as:

$$\dot{z} = \frac{\partial \Omega}{\partial Z}$$

- If Ω is a convex function of Z which includes the origin, the dissipation is automatically positive, since:

$$\phi_1 = Z \frac{\partial \Omega}{\partial Z}$$

(all the points of the surface Ω are on the same side of the tangent plane defined by $\frac{\partial \Omega}{\partial Z}$))

- One can also define (through the Legendre-Fenchel transform) a companion potential in terms of \dot{z} :

$$\Omega^*(\dot{z}) = \max_Z (Z\dot{z} - \Omega(Z))$$

- A new potential, expressed as $\Omega^*(\dot{z})$ or $\Omega(Z)$ must be introduced to characterize the dissipative processes.

Operational way for material model development

- Define a set of two potentials, ψ, Ω
- Derive the relation between state variables and hardening variables from ψ
- Derive the *nature* of the hardening variables and their evolution rules from Ω

In the following, example of isotropic and kinematic nonlinear hardenings; the choice for the sets (Y_I, α_I) is:

Type of hardening	State variable	Conjugated variable
Isotropic hardening	r	R
Kinematic hardening	α	\tilde{X}

NOTE: Previously, p for isotropic hardening, $\tilde{\varepsilon}^p$ for linear kinematic hardening

Viscoplastic standard model with isotropic and kinematic hardening (1)

Example using the von Mises criterion:

$$f(\tilde{\boldsymbol{\sigma}}, \tilde{\boldsymbol{X}}, R) = J(\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{X}}) - R - \sigma_y = ((3/2)(\tilde{\boldsymbol{s}} - \tilde{\boldsymbol{X}}) : (\tilde{\boldsymbol{s}} - \tilde{\boldsymbol{X}}))^{0,5} - R$$

Assume the following free energy:

$$\psi(T, \tilde{\boldsymbol{\varepsilon}}^e, r, \tilde{\boldsymbol{\alpha}}) = \frac{1}{2} \tilde{\boldsymbol{\varepsilon}}^e : \tilde{\boldsymbol{\Lambda}} : \tilde{\boldsymbol{\varepsilon}}^e + \frac{1}{2} b Q r^2 + \frac{1}{3} C \tilde{\boldsymbol{\alpha}} : \tilde{\boldsymbol{\alpha}}$$

Viscoplastic potential:

$$\Omega(\tilde{\boldsymbol{\sigma}}, \tilde{\boldsymbol{X}}, R) = \frac{n+1}{K} \left(\frac{f}{K} \right)^{n+1}$$

Viscoplastic flow:

$$\dot{\tilde{\boldsymbol{\varepsilon}}}^p = \frac{\partial \Omega}{\partial \tilde{\boldsymbol{\sigma}}} = \frac{\partial \Omega}{\partial f} \frac{\partial f}{\partial \tilde{\boldsymbol{\sigma}}} = \dot{p} \tilde{\boldsymbol{n}}$$

with

$$\dot{p} = \frac{\partial \Omega}{\partial f} = \left(\frac{f}{K} \right)^n \quad \text{and} \quad \tilde{\boldsymbol{n}} = \frac{\partial f}{\partial \tilde{\boldsymbol{\sigma}}} = \frac{3}{2} \frac{\tilde{\boldsymbol{s}} - \tilde{\boldsymbol{X}}}{J(\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{X}})}$$

Viscoplastic standard model with isotropic and kinematic hardening (2)

The state variable for isotropic hardening is found from:

$$\dot{r} = -\frac{\partial \Omega}{\partial R} = -\frac{\partial \Omega}{\partial f} \frac{\partial f}{\partial R} = \dot{p}$$

The state variable for kinematic hardening is found from:

$$\dot{\alpha} = -\frac{\partial \Omega}{\partial \tilde{\mathbf{X}}} = -\frac{\partial \Omega}{\partial f} \frac{\partial f}{\partial \tilde{\mathbf{X}}} = \dot{p} \tilde{\mathbf{n}} = \tilde{\boldsymbol{\varepsilon}}^p$$

It is then *mandatory* to choose accumulated strain for isotropic hardening and plastic strain for kinematic hardening

$$R = bQp \quad \tilde{\mathbf{X}} = \frac{2}{3}C\tilde{\boldsymbol{\alpha}} = \frac{2}{3}C\tilde{\boldsymbol{\varepsilon}}^p$$

The choices made in the free energy provide *linear* hardening rules.

Generalization of Hill's principle

Maximize of the intrinsic dissipated power instead of just maximize $\tilde{\sigma} : \dot{\tilde{\varepsilon}}^p$

$$\Phi_1 = \tilde{\sigma} : \dot{\tilde{\varepsilon}}^p - Y_I \dot{\alpha}_I = \tilde{\sigma} : \dot{\tilde{\varepsilon}}^p - \dot{\psi}_p = Z \dot{z}$$

With Z including stress and the hardening variables Y_I ,
 z including plastic strain and the state variables ($-\alpha_I$) :

$$(Z - Z^*) \dot{z} \geq 0$$

... with the constraint $f \leq 0$.

Let us define $\mathbb{F}(Z) = Z \dot{z} - \dot{\lambda} f$ and search for the zero of $\partial \mathbb{F} / \partial Z$

$$\dot{z} = \dot{\lambda} \frac{\partial f}{\partial Z} \quad \text{then:} \quad \dot{\tilde{\varepsilon}}^p = \dot{\lambda} \frac{\partial f}{\partial \tilde{\sigma}} = \dot{\lambda} \tilde{n} \quad ; \quad \dot{\alpha}_I = -\dot{\lambda} \frac{\partial f}{\partial Y_I}$$

Dissipation for a standard model

(1) Z actual maximizes the intrinsic dissipation;

equivalent to:

(2) the flow direction \dot{z} is normal to the surface defined by f ; the domain defined by f is convex.

If the domain defined by f includes ($f=0$), the dissipation Φ_1 is automatically positive.

Nature of the hardening variables

Example using the von Mises criterion:

$$f(\tilde{\boldsymbol{\sigma}}, \tilde{\boldsymbol{X}}, R) = J(\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{X}}) - R - \sigma_y = ((3/2)(\tilde{\boldsymbol{s}} - \tilde{\boldsymbol{X}}) : (\tilde{\boldsymbol{s}} - \tilde{\boldsymbol{X}}))^{0,5} - R$$

- *kinematic hardening*, $\tilde{\boldsymbol{\alpha}} \equiv \tilde{\boldsymbol{\varepsilon}}^p$

$$\dot{\tilde{\boldsymbol{\alpha}}} = -\dot{\lambda} \frac{\partial f}{\partial \tilde{\boldsymbol{X}}} = \dot{\lambda} \frac{\partial f}{\partial \tilde{\boldsymbol{\sigma}}} = \dot{\tilde{\boldsymbol{\varepsilon}}}^p$$

- *isotropic hardening*, p

$$\dot{p} = -\dot{\lambda} \frac{\partial f}{\partial R} = \dot{\lambda}$$

p , accumulated plastic strain, length of the strain path:

$$((2/3) \dot{\tilde{\boldsymbol{\varepsilon}}}^p : \dot{\tilde{\boldsymbol{\varepsilon}}}^p)^{0,5} = \left((2/3) \dot{\lambda} \tilde{\boldsymbol{n}} : \dot{\lambda} \tilde{\boldsymbol{n}} \right)^{0,5} = \dot{\lambda}$$

Under onedimensional loading, $\dot{p} = |\dot{\varepsilon}^p|$

Non linear hardening (1)

kinematic and isotropic hardening both are needed for a realistic modeling of the behavior

- standard framework

$$f(\tilde{\boldsymbol{\sigma}}, \tilde{\mathbf{X}}, R) = J(\tilde{\boldsymbol{\sigma}} - \tilde{\mathbf{X}}) - \sigma_y - R + \frac{D}{2C} J^2(\tilde{\mathbf{X}}) + \frac{R^2}{2Q}$$

$$\text{with } J(\tilde{\mathbf{X}}) = \left(\frac{3}{2} \tilde{\mathbf{X}} : \tilde{\mathbf{X}} \right)^{0,5}$$

- associated framework

$$f(\tilde{\boldsymbol{\sigma}}, \tilde{\mathbf{X}}, R) = J(\tilde{\boldsymbol{\sigma}} - \tilde{\mathbf{X}}) - \sigma_y - R$$

Non linear hardening (2)

$$\dot{\tilde{\alpha}} = -\dot{\lambda} \frac{\partial f}{\partial \tilde{X}} = \left(\tilde{n} - \frac{3D}{2C} \tilde{X} \right) \dot{\lambda}$$

$$\dot{r} = -\dot{\lambda} \frac{\partial f}{\partial R} = \left(1 - \frac{R}{Q} \right) \dot{\lambda}$$

The state variables $\tilde{\alpha}$ and r , define the hardening variables \tilde{X} et R :

$$\psi = \dots + \frac{1}{2} b Q r^2 + \frac{1}{3} C \tilde{\alpha} : \tilde{\alpha}$$

$$\tilde{X} = \frac{2}{3} C \tilde{\alpha} \quad ; \quad R = b Q r$$

- plastic multiplyier \equiv accumulated plastic strain rate, but $r \neq p$
- *for the case where the coefficients are constants :*

$$\dot{\tilde{X}} = \frac{2}{3} C \dot{\tilde{\alpha}}^p - D \tilde{X} \dot{p}$$

$$\dot{R} = b(Q - R)\dot{p} \quad \text{then } R = Q(1 - \exp(-b p))$$

Dissipated energy

$$\begin{aligned}\Phi_1 &= \tilde{\boldsymbol{\sigma}} : \dot{\tilde{\boldsymbol{\varepsilon}}}^p - R \dot{r} - \tilde{\boldsymbol{X}} : \dot{\tilde{\boldsymbol{\alpha}}} \\ &= \left(\tilde{\boldsymbol{\sigma}} : \tilde{\boldsymbol{n}} - R + \frac{R^2}{Q} - \tilde{\boldsymbol{X}} : \tilde{\boldsymbol{n}} + \frac{D}{C} J^2(\tilde{\boldsymbol{X}}) \right) \dot{\lambda}\end{aligned}$$

$$\text{since } \tilde{\boldsymbol{\sigma}} : \tilde{\boldsymbol{n}} - \tilde{\boldsymbol{X}} : \tilde{\boldsymbol{n}} = J(\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{X}})$$

$$\begin{aligned}\Phi_1 &= \left(J(\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{X}}) + \frac{R^2}{Q} + \frac{D}{C} J^2(\tilde{\boldsymbol{X}}) \right) \dot{\lambda} \\ &= \left(f + \sigma_Y + \frac{R^2}{2Q} + \frac{D}{2C} J^2(\tilde{\boldsymbol{X}}) \right) \dot{\lambda}\end{aligned}$$

Dissipation :

- $f \dot{\lambda}$, viscous dissipation;
- $\sigma_Y \dot{\lambda}$, dissipation (due to friction) related to initial threshold;
- quadratic terms, non-linearity of the hardening;

Trapped energy

(\equiv variation of free energy) :

$$\begin{aligned}\dot{\psi} &= R \dot{r} + \mathbf{X} : \dot{\boldsymbol{\alpha}} \\ &= Q(1 - e^{-bp}) e^{-bp} \dot{p} + \tilde{\mathbf{X}} : (\tilde{\mathbf{n}} - \frac{3D}{2C} \tilde{\mathbf{X}}) \dot{p}\end{aligned}$$

Dissipation for time independent plasticity (1)

$$\Phi_1 = \boldsymbol{\sigma} : \dot{\boldsymbol{\varepsilon}}^p - A_I \dot{\alpha}_I$$

Perfect plasticity

no hardening variables

$$f(\sigma) = |\sigma| - \sigma_y$$

$$\psi \equiv \psi_e$$

$$\Phi_1 = \sigma \dot{\varepsilon}^p = \sigma_y \dot{p}$$

$$\Phi_1 = \boldsymbol{\sigma} \dot{\boldsymbol{\varepsilon}}^p = \sigma_y \dot{p}$$

since $\boldsymbol{\sigma} : \boldsymbol{n} = J(\boldsymbol{\sigma})$

linear kinematic hardening

$$\boldsymbol{\alpha} \equiv \dot{\boldsymbol{\varepsilon}}^p$$

$$f(\sigma, X) = |\sigma - X| - \sigma_y$$

$$\psi_p = \frac{1}{2} C \alpha^2$$

$$\Phi_1 = \sigma \dot{\varepsilon}^p - X \dot{\alpha} = \sigma_y \dot{p}$$

$$\Phi_1 = \boldsymbol{\sigma} \dot{\boldsymbol{\varepsilon}}^p - \boldsymbol{X} \dot{\boldsymbol{\alpha}} = \sigma_y \dot{p}$$

since $(\boldsymbol{\sigma} - \boldsymbol{X}) : \boldsymbol{n} = J(\boldsymbol{\sigma} - \boldsymbol{X})$

Dissipation for time independent plasticity (1)

Nonlinear isotropic and kinematic hardening (1D), criterion :

$$f(\sigma, X, R) = |\sigma - X| - R - \sigma_y = 0$$

$$\Phi_1 = \sigma \dot{\varepsilon}^p - X \dot{\alpha} - R \dot{r}$$

$$\text{with } \dot{\alpha} = \dot{\varepsilon}^p - (D/C)X\dot{p} \quad \dot{r} = (1 - b\frac{R}{Q})\dot{p}$$

Then

$$\begin{aligned}\Phi_1 &= (\sigma - X)\dot{\varepsilon}^p - R\dot{p} + \frac{D}{C}X^2\dot{p} + \frac{R^2}{Q}\dot{p} \\ &= |\sigma - X|\dot{p} - R\dot{p} + \frac{D}{C}X^2\dot{p} + \frac{R^2}{Q}\dot{p} \\ &= \sigma_y\dot{p} + \frac{D}{C}X^2\dot{p} + \frac{R^2}{Q}\dot{p}\end{aligned}$$

Dissipation for time independent plasticity (1)

$$\Phi_1 = \sigma_y \dot{p} + \frac{D}{C} X^2 \dot{p} + \frac{R^2}{Q} \dot{p}$$

For 1D tension:

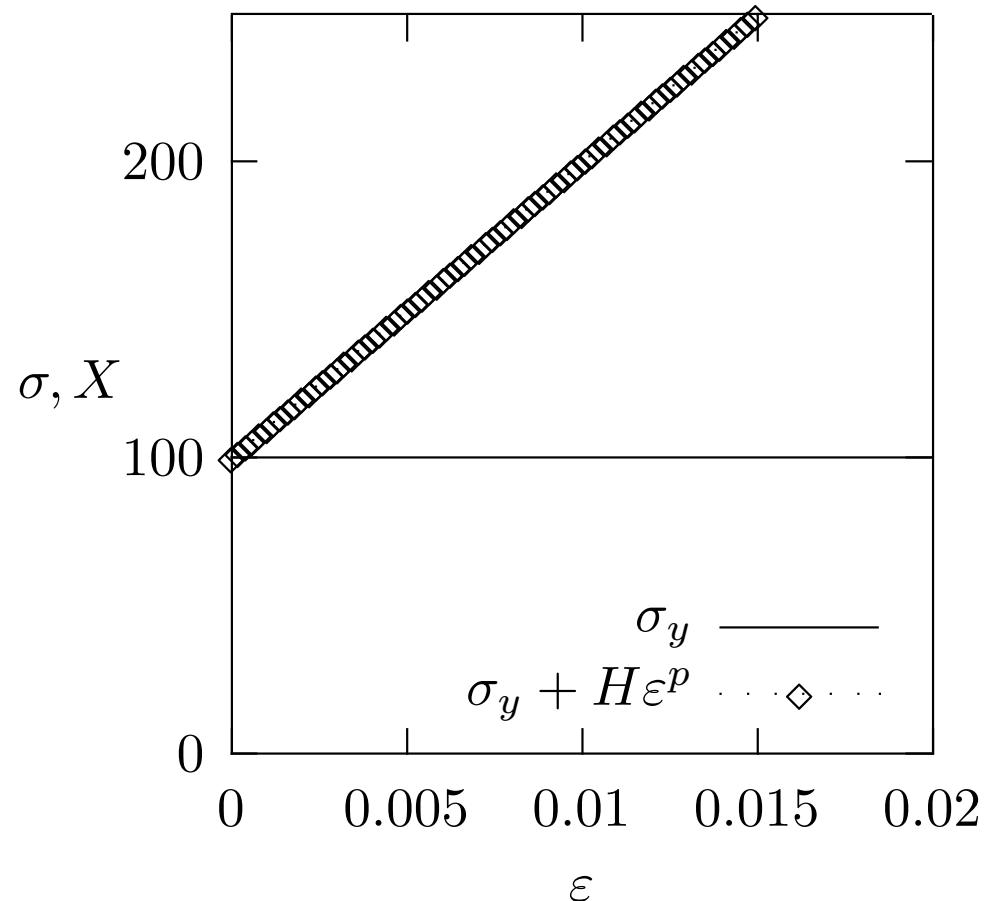

Stored forever by the isotropic mechanism

$$\int R \dot{r} = \int R \left(1 - \frac{R}{Q}\right) \dot{p} = \int Q \left(1 - \exp(-bp)\right) \exp(-bp) \dot{p} = \frac{R^2}{2Q}$$

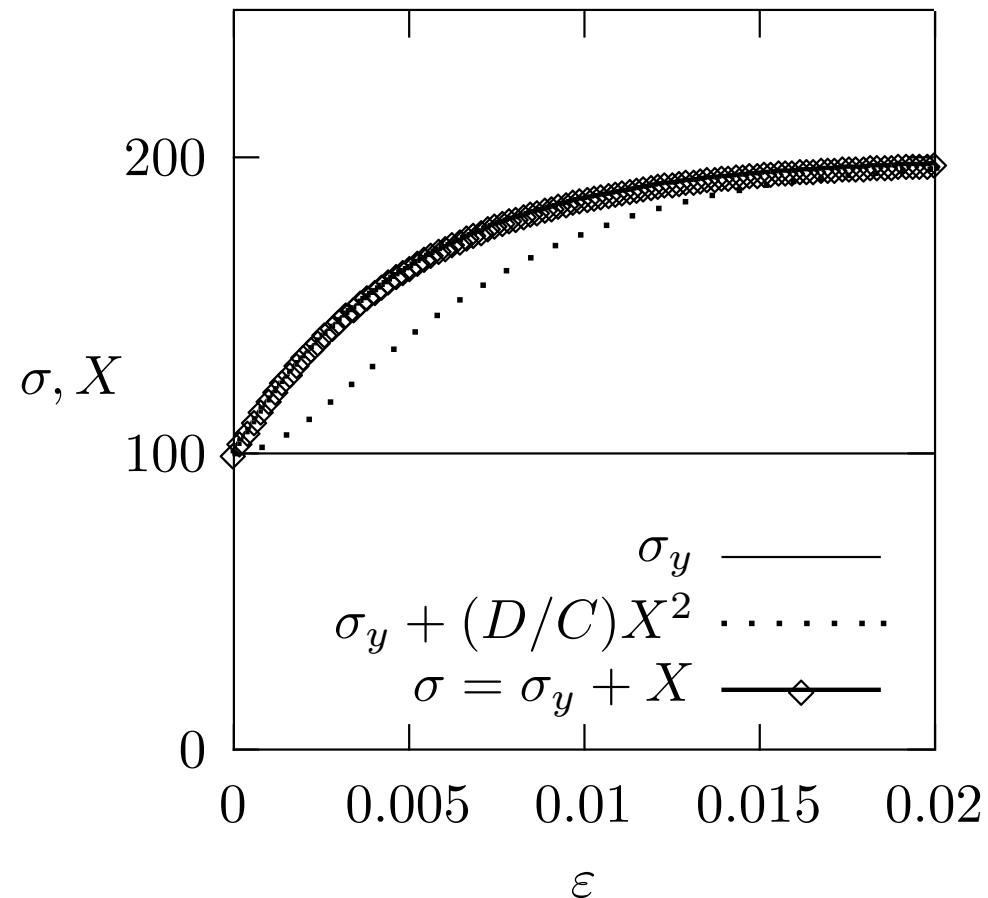

Temporary stored by the kinematic mechanism

$$\int X \dot{\alpha} = \frac{X^2}{2C} = \frac{C}{2D^2} (1 - \exp(-D\varepsilon^p))^2$$

A view on dissipated and stored energy for linear kinematic hardening

A view on dissipated and stored energy for non linear kinematic hardening

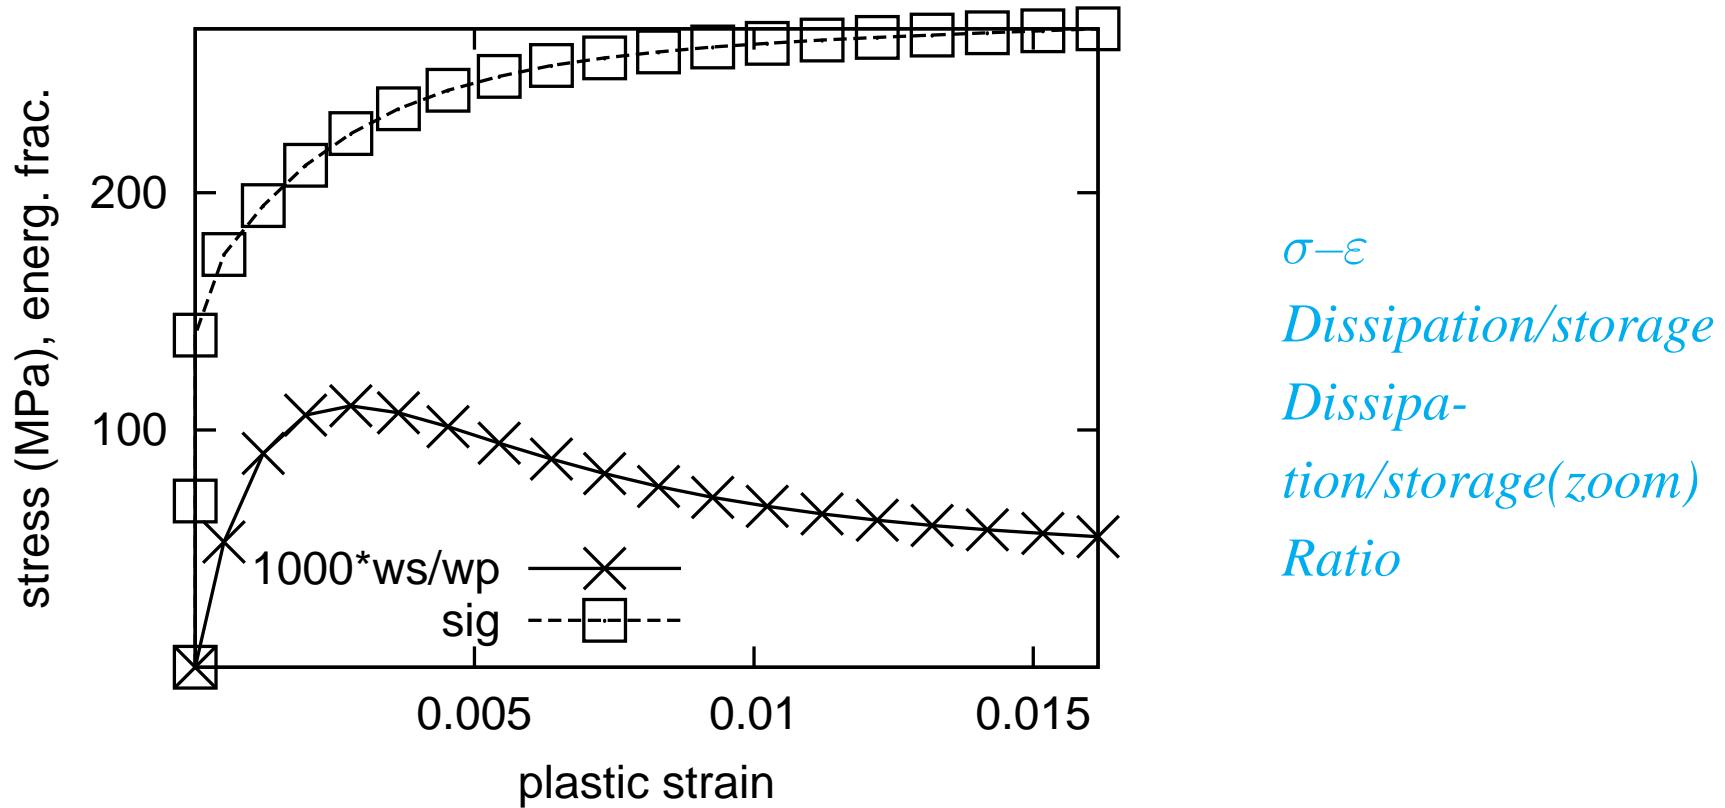

Adiabatic RVE

The dissipated energy will produce a temperature change $\dot{T} = \frac{\Phi_1}{\rho C}$
